

# Scenario trajectories over $t = 0 \dots 100$ (city-mean, seed 1)

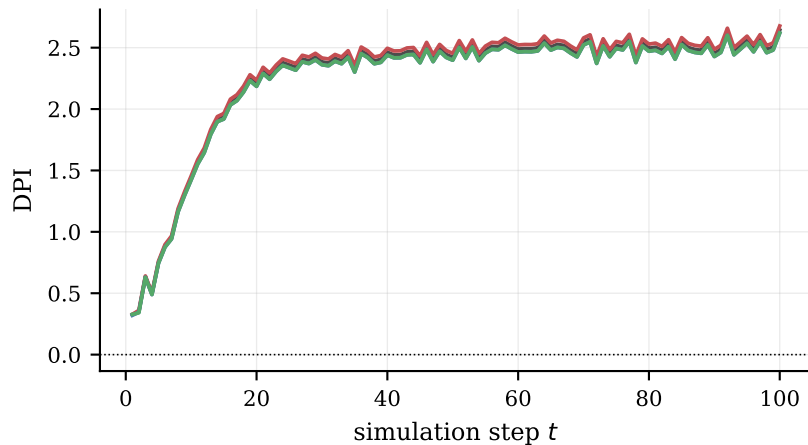

(a) H+T level

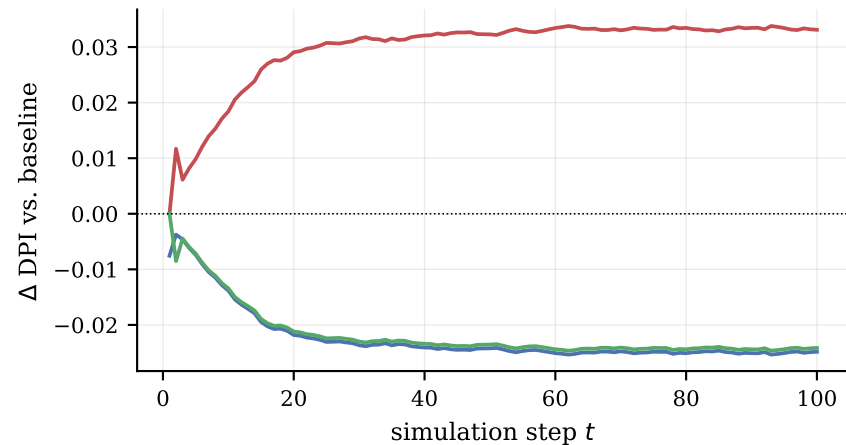

(b) H+T policy effect

(c) DPI level

(d) DPI policy effect

Panels (b) and (d) show each intervention relative to the untreated baseline, the comparative quantity of interest. Logistic carrying capacities and mean reversion hold the economy in dynamic equilibrium: no node reaches a hard state floor over the full horizon, and policy effects persist as sustained level offsets rather than transients.
